

ON THE DISTRIBUTION OF INDICATORS OF UNCONDITIONAL EXPONENTIAL BASES IN SPACES WITH A POWER WEIGHT

K.P. ISAEV, K.V. TRUNOV

Abstract. In the present paper we consider the existence of unconditional exponential bases in a space of locally integrable functions on a bounded interval of the real number line I satisfying

$$\|f\| := \sqrt{\int_I |f(t)|^2 e^{-2h(t)} dt} < \infty,$$

where $h(t)$ is a convex function on this interval. The lower estimate was obtained for the frequency of indicators of unconditional bases of exponentials when $I = (-1; 1)$, $h(t) = -\alpha \ln(1 - |t|)$, $\alpha > 0$.

Keywords: series of exponents, unconditional bases, Riesz bases, power weights, Hilbert space.

1. INTRODUCTION

Let I be a limited interval of a real axis, $h(t)$ — a convex function on this interval and $L^2(I, h)$ — a space of locally integrated functions on I , satisfying the condition

$$\|f\| := \sqrt{\int_I |f(t)|^2 e^{-2h(t)} dt} < \infty.$$

It is the Hilbert space with a scalar product

$$(f, g) = \int_I f(t) \bar{g}(t) e^{-2h(t)} dt.$$

The systems of element $\{e_k, k = 1, 2, \dots\}$ in the Hilbert space is called an unconditional base (see [2]), if it is total and there are numbers $c, C > 0$, such that for any group of numbers c_1, c_2, \dots, c_n the following correlation holds true

$$c \sum_{k=1}^n |c_k|^2 \|e_k\|^2 \leq \left\| \sum_{k=1}^n c_k e_k \right\|^2 \leq C \sum_{k=1}^n |c_k|^2 \|e_k\|^2.$$

It is known (see [3],[4]), that if the system $\{e_k, k = 1, 2, \dots\}$ is an unconditional base, then any element of the space H can be only presented in the form of the following row

$$x = \sum_{k=1}^{\infty} x_k e_k,$$

and

$$c \sum_{k=1}^{\infty} |x_k|^2 \|e_k\|^2 \leq \|x\|^2 \leq C \sum_{k=1}^{\infty} |x_k|^2 \|e_k\|^2.$$

In the paper [12] there was introduced the following characteristic for continuous functions on the plane u , measuring deviation of the given function from harmonic functions. For the continuous

function u , for $z \in \mathbb{C}$ and the positive number p we will define the supremum of all such $r > 0$ by $\tau(u, z, p)$, when the following condition holds true

$$\inf\left\{ \sup_{w \in B(z, r)} |u(w) - h(w)|, h \text{ harmonic in } B(z, r) \right\} \leq p.$$

Let us define the circle of the radius r in the point z by $B(z, r)$. It results right from the definition, that if $\tau(u, z_0, p) = \infty$ for some point z_0 , then $\tau(u, z, p) \equiv \infty$.

It results from Lemma 1.1 in paper [6], that in the case, when u is a continuous subharmonic function, the value $\tau = \tau(u, \lambda, p)$ can be defined by the condition: if $H(z)$ is the lowest harmonic majorant of the function u in the circle $B(\lambda, \tau)$, then

$$\max_{z \in \overline{B}(\lambda, \tau)} (H(z) - u(z)) = 2p. \quad (1)$$

The following theorem (Theorem 2.1) was proved in paper [5]

Theorem 1. *If the system $\{e^{z_j t}\}_{j=1}^{\infty}$ is an unconditional base in the space $L_2(I, h)$, then there is an entire function L with simple zeros in the points z_j , $j = 1, 2, \dots$, for which the following correlation holds true*

$$\frac{1}{P} K(z) \leq \sum_{j=1}^{\infty} \frac{|L(z)|^2 K(z_j)}{|L'(z_j)|^2 |z - z_j|^2} \leq P K(z), \quad z \in \mathbb{C}, \quad (2)$$

where P is some positive constant and $K(z) = \|e^{zt}\|^2$.

The function $\ln K(z)$ is subharmonic and continuous on all the plane.

In the continuation of the paper we will define the function $\tau(\ln K(w), z, \ln(5P))$ by $\tau(z)$, where P is a constant from the correlation (2). Hence,

$$\inf_h \left\{ \sup_{z \in \overline{B}(\lambda, \tau(\lambda))} |\ln K(z) - h(z)|, h \text{ is harmonic in } B(\lambda, \tau(\lambda)) \right\} = \ln(5P),$$

The following theorem was proved in [7] (see Theorem 3, Theorem 4 and its corollary).

Theorem 2. *Let the system $\{\exp(tz_i), i = 1, 2, \dots\}$, make an unconditional base in the space $L_2(I, h)$. Then*

1) *in any circle $B(z, 2\tau(z))$ there is at least one index z_i .*

2) *suppose $b = \frac{1}{20P^{\frac{2}{3}}}$. Then for any i, j , $i \neq j$, the following inequality holds true*

$$|z_i - z_j| \geq 2b \max(\tau(z_i), \tau(z_j)).$$

The first statement of this theorem limits the frequency of indexes z_k below, and the second — above. On the basis of these multidirectional estimates Theorem 5 was proved in paper [7], and being applied to the situation considered in the paper, it can be formulated the following way.

Theorem 3. *Let $h(t)$ be a convex function on the interval $I = (-1, 1)$ and*

$$\tilde{h}(x) = \sup_{t \in I} (xt - h(t))$$

be a function, conjugate to it by Jung. Let us assume, that $\tilde{h} \in C^2(|x| > \text{const})$ and for any positive number c the function $s(x) = \frac{1}{\sqrt{\tilde{h}''(x)}}$ satisfies the condition

$$\left(\min_{y \in B(x, cs(x))} \tilde{h}''(y) \right) \left(\max_{y \in B(x, cs(x))} \tilde{h}''(y) \right)^{-1} \asymp 1, \quad |x| \rightarrow \infty. \quad (3)$$

Then there are no unconditional bases from exponents in the space $L_2(I, h)$.

The estimate of the function growth results from condition (3)

$$\lim_{|x| \rightarrow \infty} \frac{|x| - \tilde{h}(x)}{\ln |x|} = +\infty,$$

which is equivalent to the correlation

$$\lim_{|t| \rightarrow 1} \frac{h(t)}{-\ln(1 - |t|)} = +\infty,$$

or for any $\alpha > 0$

$$(1 - |t|)^\alpha = O(e^{h(t)}), \quad |t| \longrightarrow 1.$$

In this paper we consider a problem of unconditional bases from exponents in spaces with not more than power weights, i.e. according to the condition, that for some $\alpha > 0$

$$e^{h(t)} = O((1 - |t|)^\alpha), \quad |t| \longrightarrow 1.$$

As model spaces we will consider the spaces $L_2(I, h)$ when $I = (-1; 1)$, $h(t) = -\alpha \ln(1 - |t|)$ for $\alpha > 0$, which we will define by $L_2(\alpha)$.

We are going to prove the following, more precise estimate of unconditional bases frequency below.

Theorem 4. *Let the system $\{e^{z_k t}\}$ make an unconditional base in the space $L_2(\alpha)$. Then there are numbers $\delta_1 = \delta_1(\alpha) \in (0, 1)$ and $\delta_2 = \delta_2(\alpha) > 0$, $M = M(\alpha) > 0$, such that in case of sufficiently large $|x_0|$ for any y_0 in every rectangle $Q = \{z = x + iy : \delta_1 x_0 \leq x \leq \delta_2 x_0, |y - y_0| \leq M|x_0|\}$ and $-Q$ there is at least one index z_k .*

The fact, that this estimate is more precise as to p.1 of Theorem 2, results from the awareness, that the value $\tau(z)$ in these spaces is comparable with $|Re z|$. When $\alpha > \frac{1}{2}$, the statement of this theorem is proved in paper [13] some other way.

2. PREPARATORY STATEMENTS

The system of exponents $\{e^{\lambda t}\}$, $\lambda \in \mathbb{C}$ is total in the space $L_2(I, h)$, therefore, the transform of Fourier-Laplace functionals $L : S \longrightarrow \widehat{S}(\lambda)$, defined by the formula

$$\widehat{S}(\lambda) = S(e^{\lambda t}), \quad \lambda \in \mathbb{C},$$

sets mutually single-valued correlation between the conjugated space $L_2^*(I, h)$ and some linear manifold of entire functions $\widehat{L}_2(I, h)$. In this linear manifold we will consider an induced structure of the Hilbert space. Namely, if functionals $S_1, S_2 \in L_2^*(I, h)$ are generated by the functions $f_1, f_2 \in L_2(I, h)$, then we suppose

$$(\widehat{S}_1(\lambda), \widehat{S}_2(\lambda))_{\widehat{L}_2(I, h)} = (f_1, f_2)_{L_2(I, h)}.$$

It is easy to assure, that the function

$$K(\lambda, z) = \int_I e^{\lambda t + \bar{z}t - 2h(t)} dt, \quad \lambda, z \in \mathbb{C}$$

is a reproducing kernel in the space $\widehat{L}_2(I, h)$, i.e.

$$(F(\lambda), K(\lambda, z)) = F(z), \quad F \in \widehat{L}_2(I, h).$$

It was proved in paper [14], that in the space $\widehat{L}_2(I, h)$ the following equivalent norm can be introduced

$$\|F\|^2 = \int_{\mathbb{R}} \int_{\mathbb{R}} |F(x + iy)|^2 e^{-2\tilde{h}(x)} \rho_{\tilde{h}}(x) d\tilde{h}'(x) dy, \quad (4)$$

where

$$\tilde{h}(x) = \sup_{t \in I} (xt - h(t)), \quad x \in \mathbb{R},$$

is conjugated by Jung to the function $h(t)$, and the number $\rho = \rho_{\tilde{h}}(x)$ is defined as a supremum for all $t > 0$, for which

$$\int_{x-t}^{x+t} |\tilde{h}'_+(y) - \tilde{h}'_+(x)| dy \leq 1.$$

It is shown in paper [5], that the norm of the space $\widehat{L}_2(I, h)$ can be also presented as

$$\|F\|^2 = \int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|F(x + iy)|^2}{K(x)} d\tilde{h}'(x) dy, \quad (5)$$

where $K(z) = K(z, z)$.

Whereas the Fourier-Laplace transform sets an isomorphism of the space $L_2^*(I, h)$ and $\widehat{L}_2(I, h)$, then the unconditional base of the exponent system $\{e^{tz_k}\}$ in the space $L_2(I, h)$ is equivalent to the

statement, that the set of indexes $\{z_k\}$ is the set of uniqueness for the space $\widehat{L}_2(I, h)$, and for any function $F \in \widehat{L}_2(I, h)$ the following correlation holds true

$$\frac{1}{P} \sum_{k=1}^{\infty} \frac{|F(z_k)|^2}{K(z_k)} \leq \|F\|^2 \leq P \sum_{k=1}^{\infty} \frac{|F(z_k)|^2}{K(z_k)}, \quad (6)$$

where P is some positive constant.

Let us calculate the introduced above characteristics for the space $L_2(\alpha)$.

Lemma 1. *If*

$$K_\alpha(z) = \|e^{zt}\|_{L_2(\alpha)}^2 = K_\alpha(z, z) = \int_{-1}^1 e^{2\operatorname{Re}zt} (1 - |t|)^{2\alpha} dt,$$

$$h_\alpha(t) = -\alpha \ln(1 - |t|), \quad \rho_\alpha(x) = \rho_{\tilde{h}_\alpha}(x), \quad \tau_\alpha(z, p) = (\ln K_\alpha(w), z, p),$$

then

$$\tilde{h}_\alpha(x) = |x| - \alpha \ln|x| + a_\alpha, \quad |x| \geq X(\alpha),$$

$$\tau_\alpha(z, p) \asymp |\operatorname{Re}z| + 1, \quad |\operatorname{Re}z| \rightarrow \infty, \quad \rho_\alpha(x) = \sqrt{1 - e^{-\frac{1}{2\alpha+1}x}}, \quad x > X(\alpha),$$

$$\ln K_\alpha(x) = 2|x| - (2\alpha + 1) \ln|x| + b_\alpha + o(1), \quad |x| \rightarrow \infty,$$

where

$$b_\alpha = \ln \frac{1}{2^{2\alpha+1}} \int_0^\infty e^{-y} y^{2\alpha} dy.$$

Whereas the functions $\tilde{h}_\alpha(x), \rho_\alpha(x)$ are positive and contiguous, then, in particular, the following correlations hold true

$$e^{\tilde{h}_\alpha(x)} \asymp e^{|x| - \alpha \ln(|x|+1)}, \quad x \in \mathbb{R},$$

$$\tilde{h}_\alpha''(x) \asymp (|x| + 1)^{-2}, \quad x \in \mathbb{R},$$

$$\rho_\alpha(x) \asymp (|x| + 1), \quad x \in \mathbb{R},$$

$$K_\alpha(x) \asymp e^{2|x| - (2\alpha+1) \ln(|x|+1)}, \quad x \in \mathbb{R}.$$

Proof. The function $K(x)$ is even, therefore, we will make calculations for $x > 0$. The asymptotic representation for $\ln K_\alpha(x)$ results from the correlation

$$\int_{-1}^1 e^{2xt} (1 - |t|)^{2\alpha} dt = \int_{-1}^0 e^{2xt} (1 + t)^{2\alpha} dt + e^{2x} \int_0^1 e^{-2x(1-t)} (1 - t)^{2\alpha} dt =$$

$$= O(1) + \frac{e^{2x}}{(2x)^{2\alpha+1}} \int_0^{2x} e^{-y} y^{2\alpha} dy = \frac{e^{2x+b_\alpha}}{x^{2\alpha+1}} (1 + o(1)), \quad x \rightarrow \infty.$$

The function $\tilde{h}_\alpha(x)$ for large x is calculated by the definition. Expressions for τ_α, ρ_α were calculated in paper [13]. \square

Lemma 2. *For $\delta_1, \delta_2, M > 0$ and $x_0 \in \mathbb{R}_+$ via $Q(x_0, \delta_1, \delta_2, M)$ we will define the rectangle*

$$Q = \{x + iy : \delta_1 x_0 \leq x \leq \delta_2 x_0, |y| \leq M x_0\}.$$

Then for any $\varepsilon > 0$ we can find quite a low number of $\delta_1 = \delta_1(\varepsilon) > 0$, and quite large numbers of $\delta_2 = \delta_2(\varepsilon) > 0$, $M = M(\delta_1, \delta_2, \varepsilon) > 0$ so, that when $x_0 > X(\delta_1, \delta_2, \varepsilon)$ the following correlation will hold true

$$\int_{\mathbb{C} \setminus Q(x_0, \delta_1, \delta_2, M)} |K_\alpha(x + iy, x_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) d\tilde{h}'_\alpha(x) dy \leq \varepsilon K_\alpha(x_0, x_0).$$

Proof. Let us take positive x_0 and present the X-axis in the form of gaps integration

$$I_1 = \{x : x > \delta_2 x_0\}, \quad I_2 = \{x : -\delta_1 x_0 \leq x < \delta_1 x_0\},$$

$$I_3 = \{x : -2x_0 < x < -\delta_1 x_0\}, \quad I_4 = \{x : x \leq -2x_0\},$$

$$I = \{x : \delta_1 x_0 \leq x \leq \delta_2 x_0\}.$$

Then the supplement to the rectangle $Q(x_0, \delta_1, \delta_2, M)$ will be expanded into two half-planes $Q_1 = I_1 \times \mathbb{R}$ and $Q_4 = I_4 \times \mathbb{R}$, two vertical strips $Q_2 = I_2 \times \mathbb{R}$ and $Q_3 = I_3 \times \mathbb{R}$ and two semi-strips

$Q_+ = I \times \{y > Mx_0\}$, $Q_- = I \times \{y < -Mx_0\}$. Note, that the function $K_\alpha(x + iy, x_0)$ is the Fourier function transform $e^{(x+x_0)t-2h_\alpha(t)}$ with fixed x and, according to the Plancherel theorem

$$\int_{-\infty}^{\infty} |K_\alpha(x + iy, x_0)|^2 dy = 2\pi \int_{-1}^1 e^{2(x+x_0)t-4h_\alpha(t)} dt.$$

As it was proved in paper [15], for any convex function $u(t)$ the following correlation holds true

$$\int_{-1}^1 e^{yt-u(t)} dt \asymp \frac{e^{\tilde{u}(y)}}{\rho_{\tilde{u}}(y)}, \quad y \in \mathbb{R}.$$

Hence, according to Lemma 1 we have

$$\int_{-\infty}^{\infty} |K_\alpha(x + iy, x_0)|^2 dy \asymp \frac{e^{4\tilde{h}_\alpha(\frac{x+x_0}{2})}}{\rho_\alpha(\frac{x+x_0}{2})} \asymp \frac{e^{4\tilde{h}_\alpha(\frac{x+x_0}{2})}}{(|x+x_0|+1)},$$

therefore,

$$\int_{-\infty}^{\infty} |K_\alpha(x + iy, x_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) dy \prec \frac{x_0(|x|+1)e^{4\tilde{h}_\alpha(\frac{x+x_0}{2})-2\tilde{h}_\alpha(x)-2\tilde{h}_\alpha(x_0)}}{|x+x_0|+1} K_\alpha(x_0).$$

In the half-plane Q_1 we obtain the estimate when $\delta_2 \rightarrow \infty$ is uniform on x_0

$$\int_{Q_1} |K_\alpha(x + iy, x_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) dy d\tilde{h}'_\alpha(x) \prec K_\alpha(x_0) \int_{\delta_2}^{\infty} \frac{dy}{(y+1)y} = o(K_\alpha(x_0)).$$

If $\delta_1 \leq \frac{1}{2}$ and $|x| \leq \delta_1 x_0$, then we have

$$\frac{x_0(|x|+1)e^{4\tilde{h}_\alpha(\frac{x+x_0}{2})-2\tilde{h}_\alpha(x)-2\tilde{h}_\alpha(x_0)}}{|x+x_0|+1} \prec \frac{x_0(x_0+1)^{2\alpha}(|x|+1)^{2\alpha+1}}{(|x+x_0|+1)^{4\alpha+1}} \prec \frac{(|x|+1)^{2\alpha+1}}{(|x+x_0|+1)^{2\alpha}},$$

therefore, in the strip Q_2 we deal with $\delta_1 \rightarrow 0$, which is uniform on $x_0 > 1$

$$\int_{Q_2} |K_\alpha(x + iy, x_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) dy d\tilde{h}'_\alpha(x) \prec \frac{K_\alpha(x_0)}{x_0^{2\alpha}} \int_{-\delta_1 x_0}^{\delta_1 x_0} (|x|+1)^{2\alpha-1} dx = o(K_\alpha(x_0)).$$

For the fixed $\delta_1 \leq \frac{1}{2}$ for $-2x_0 \leq x \leq -\delta_1 x_0$ we obtain

$$\frac{x_0(|x|+1)e^{4\tilde{h}_\alpha(\frac{x+x_0}{2})-2\tilde{h}_\alpha(x)-2\tilde{h}_\alpha(x_0)}}{|x+x_0|+1} \prec e^{-2\delta_1 x_0} (x_0+1)^{4\alpha+2},$$

hence, in the strip Q_3 with $x_0 \rightarrow \infty$ we have

$$\int_{Q_3} |K_\alpha(x + iy, x_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) dy d\tilde{h}'_\alpha(x) \prec K_\alpha(x_0) e^{-2\delta_1 x_0} (x_0+1)^{4\alpha+3} = o(K_\alpha(x_0)).$$

With the fixed $\delta_1 \leq \frac{1}{2}$ for $x \leq -2x_0$ we have

$$\frac{x_0(|x|+1)e^{4\tilde{h}_\alpha(\frac{x+x_0}{2})-2\tilde{h}_\alpha(x)-2\tilde{h}_\alpha(x_0)}}{|x+x_0|+1} \prec e^{-4x_0} (x_0+1)^{2\alpha+1} (|x|+1)^{-2\alpha},$$

therefore, in the strip Q_4 with $x_0 \rightarrow \infty$ the following estimate holds true

$$\int_{Q_4} |K_\alpha(x + iy, x_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) dy d\tilde{h}'_\alpha(x) \prec K_\alpha(x_0) e^{-4x_0} (x_0+1)^{2\alpha+1} \int_{2x_0}^{+\infty} (|x|+1)^{-2\alpha-2} dx = o(K_\alpha(x_0)).$$

If we choose δ_1 and δ_2 the right way, we can proceed to estimates of integrals on semi-strips Q_\pm . For this we will apply the following representation for the reproducing kernel with $z = x + iy \neq w = x_0 + iy_0$

$$\begin{aligned} K_\alpha(z, w) &= \int_{-1}^1 e^{zt+\bar{w}t-2h_\alpha(t)} dt = \int_{-1}^1 e^{2(xt-h_\alpha(t))} d\frac{e^{(\bar{w}-\bar{z})t}}{\bar{w}-\bar{z}} = \\ &= \frac{2}{\bar{w}-\bar{z}} \int_{-1}^1 e^{zt+\bar{w}t-2h_\alpha(t)} (x-h'_\alpha(t)) dt. \end{aligned}$$

According to the Cauchy-Bunyakovsky inequality, we obtain

$$|K_\alpha(z, w)|^2 \leq \frac{4}{|w-z|^2} \int_{-1}^1 e^{2xt-2h_\alpha(t)} |x-h'_\alpha(t)| dt \cdot \int_{-1}^1 e^{2x_0t-2h_\alpha(t)} |x_0-h'_\alpha(t)| dt.$$

The function $h'_\alpha(t)$ we change the sign only in the point $t = 0$, therefore

$$\begin{aligned} \int_{-1}^1 e^{2xt-2h_\alpha(t)} |x - h'_\alpha(t)| dt &\leq \int_{-1}^1 e^{2xt-2h_\alpha(t)} |x| dt - \frac{1}{2} \int_0^1 e^{2xt} de^{-2h_\alpha(t)} \leq \\ &\leq |x|K_\alpha(x) + 1 + xK_\alpha(x) \leq 3K_\alpha(x)|x|, \end{aligned}$$

when $K_\alpha(x) \geq 1$. It results from the latter two estimates, that

$$|K_\alpha(z, w)|^2 \leq \frac{36|x||x_0|}{|w-z|^2} K_\alpha(x)K_\alpha(x_0).$$

Hence, from the estimates in Lemma 1 we obtain

$$\begin{aligned} &\int_{Q_+} |K_\alpha(x+iy, x_0)|^2 e^{-\tilde{h}_\alpha(x)} \rho_\alpha dy d\tilde{h}_\alpha(x) \leq \\ &\leq 36K_\alpha(x_0)x_0 \int_I \int_{Mx_0}^\infty \frac{x}{((x-x_0)^2+y^2)(x+1)^2} dy dx < \frac{1}{M} K_\alpha(x_0). \end{aligned}$$

Therefore, choosing the number M large enough, we can consider the integral on the strip Q_+ sufficiently low. The same way we can estimate an integral on the semi-strip Q_- . \square

Lemma 2 has been proved. It is easy to see, that the following lemma has been proved the same way.

Lemma 3. For $\delta_1, \delta_2, M > 0$ and $x_0 \in \mathbb{R}_+$, $y_0 \in \mathbb{R}$ via $Q(x_0, y_0, \delta_1, \delta_2, M)$ we will define the rectangle

$$Q = \{x + iy : \delta_1 x_0 \leq x \leq \delta_2 x_0, |y - y_0| \leq Mx_0\}.$$

Then for any $\varepsilon > 0$ we can find quite a low number of $\delta_1 = \delta_1(\varepsilon) > 0$, and quite large numbers of $\delta_2 = \delta_2(\varepsilon) > 0$, $M = M(\delta_1, \delta_2, \varepsilon) > 0$ so, that when $x_0 > X(\delta_1, \delta_2, \varepsilon)$, the following correlation will hold true

$$\int_{\mathbb{C} \setminus Q(x_0, y_0, \delta_1, \delta_2, M)} |K_\alpha(x+iy, x_0+iy_0)|^2 e^{-2\tilde{h}_\alpha(x)} \rho_\alpha(x) d\tilde{h}'_\alpha(x) dy \leq \varepsilon K_\alpha(x_0, x_0).$$

3. LOW ESTIMATE OF FREQUENCY INDEXES. PROOF OF THEOREM 4

Let the system $\{\exp(z_j t)\}$ make an unconditional base in the space $L_2(\alpha)$. Then, as it was already pointed out in section 2, the system $K_\alpha(z, z_j)$ makes an unconditional base in the space $\widehat{L}_2(\alpha)$, i.e. for some P correlation (6) holds true. In this correlation we can define the norm by formula (5). Let us take sufficiently low positive ε , the degree of infinitesimality we will define later. By this number ε , according to Lemma 3, we will find numbers $\delta_1 \in (0, \frac{1}{2})$, δ_2 and M , for which the statement of Lemma 3 holds true.

Assume, that for some $x_0 \in \mathbb{R}_+, y_0$ in the rectangle $Q := Q(x_0, y_0, \delta_1 + \frac{1}{4}, \delta_2 + \frac{1}{4}, M + \frac{1}{4})$ there are no indexes z_j .

According to Lemma 1, values $\tau_\alpha(z)$ and $\rho_\alpha(z)$ are comparable with $|\operatorname{Re}z| + 1$. Considering item 1 of Theorem 2, we can assert, that there is a number $\sigma > 0$, such that circles $B_j = B(z_j, \sigma(|\operatorname{Re}z_j| + 1))$ do not cross pairwise and lie outside the rectangle Q . According to the definition of the value τ_α in every circle B_j there is a harmonic function H_j , which stands by from the function $\ln K_\alpha$ for not more than $\ln(5P)$. According to the properties of subharmonic functions, for any entire function F the following inequality holds true

$$|F(z_j)|^2 e^{-2H_j(z_j)} \leq \frac{1}{\pi\sigma^2(|\operatorname{Re}z_j| + 1)^2} \int_{B_j} |F(z)|^2 e^{-2H_j(z)} dm(z),$$

where $dm(z)$ is the Lebesgue planar measure. Whereas in the circle B_j $|\operatorname{Re}z_j| + 1 \asymp |\operatorname{Re}z| + 1$, then

$$|F(z_j)|^2 e^{-2H_j(z_j)} < \int_{B_j} \frac{|F(x+iy)|^2}{K(x)(|x|+1)^2} dx dy < \int_{B_j} \frac{|F(x+iy)|^2}{K(x)} d\tilde{h}'(x) dy.$$

Let us summarize these estimates by all j :

$$\sum_j \frac{|F(z_j)|^2}{K(z_j)} < \int_{\mathbb{C} \setminus Q} \frac{|F(x+iy)|^2}{K(x)} d\tilde{h}'(x) dy.$$

We will apply this estimate to the function $F(z) = K_\alpha(z, x_0 + iy_0)$. According to Lemma 3, we will obtain, that due to the choice of the rectangle size Q the following inequality holds true

$$\sum_j \frac{|F(z_j)|^2}{K(z_j)} \leq \varepsilon K_\alpha(x_0, x_0) = \varepsilon \|K_\alpha(z, x_0 + iy_0)\|^2.$$

If $\varepsilon < \frac{1}{P}$, then it contradicts condition (6).

Theorem 4 has been proved.
